

# Dynamic Pricing for Urban Parking Lots: Capstone Project Report

**Submitted by :** Adityabaaan Tripathy

**Registered email :** at9715@srmist.edu.in

## Executive Summary

This project successfully implemented a comprehensive dynamic pricing system for urban parking lots using real-time data streaming and the Pathway framework. The system incorporated three distinct pricing models: baseline linear pricing, demand-based pricing, and competitive pricing strategies. Through real-time data analysis of 14 parking lots across 73 days with 18 time points per day, the project demonstrated significant improvements in parking utilization efficiency and revenue optimization.

## Key Achievements:

- Developed a robust real-time data processing pipeline using Pathway framework
- Implemented multiple pricing strategies with measurable performance metrics
- Created interactive visualization dashboards using Bokeh for real-time monitoring
- Achieved improved parking space utilization through dynamic price adjustments
- Demonstrated practical applications for urban mobility management

## Project Objectives:

The primary objectives of this project were to:

1. **Optimize Parking Utilization:** Implement dynamic pricing strategies to achieve optimal occupancy rates (target: 85%) across multiple parking facilities.
2. **Revenue Maximization:** Develop pricing models that balance accessibility with revenue generation for parking operators.
3. **Traffic Congestion Reduction:** Minimize time spent searching for parking spaces through improved availability and price signals.

4. **Real-time Implementation:** Create a scalable system capable of processing live data streams and adjusting prices dynamically.
5. **Multi-model Comparison:** Evaluate the effectiveness of different pricing strategies under various demand conditions.

## Methodology

### Data Collection and Processing

The project utilized a comprehensive dataset encompassing:

- **14 parking lots** across urban areas
- **73 days** of continuous monitoring
- **18 time points** per day for granular analysis
- **Multiple variables:** occupancy rates, capacity, queue lengths, traffic conditions, special events, vehicle types, and geographical coordinates

### Technical Implementation

**Framework Selection:** Pathway was chosen for its robust real-time streaming capabilities and Python integration, enabling seamless data processing and model deployment.

#### Data Pipeline Architecture:

```
# Schema Definition
class ParkingSchema(pw.Schema):
    Timestamp: str
    Occupancy: int
    Capacity: int
    QueueLength: int
    TrafficConditionNearby: str
    IsSpecialDay: int
    VehicleType: str
```

**Real-time Data Streaming:** The system processes data through Pathway's replay functionality, simulating real-world conditions with configurable input rates.

## Model Development

### Model 1: Baseline Linear Pricing

The baseline model implements a simple linear relationship between occupancy rates and pricing:

```
Price = Base_Price +  $\alpha$  × (Occupancy / Capacity)
```

Where  $\alpha$  represents the sensitivity parameter controlling price responsiveness to occupancy changes.

### Model 2: Demand-Based Pricing

The demand-based model incorporates multiple factors influencing parking demand:

```
Demand_Score =  $\alpha$  × Occupancy_Rate +  $\beta$  × Queue_Length +  $\gamma$  × Traffic_Condition +  $\delta$  ×  
Special_Day_Factor  
Price = Base_Price × (1 +  $\lambda$  × Normalized_Demand_Score)
```

This model considers:

- **Occupancy rates** as the primary demand indicator
- **Queue lengths** reflecting immediate parking pressure
- **Traffic conditions** impacting area accessibility
- **Special events** creating demand spikes
- **Price bounds** ensuring affordability (0.5x to 2x base price)

### Model 3: Competitive Pricing

The competitive model extends demand-based pricing by incorporating:

- **Proximity analysis** using geographical coordinates
- **Competitor price monitoring** for nearby facilities
- **Rerouting recommendations** for over-capacity situations

## Visualization and Monitoring

Real-time dashboards were developed using Bokeh and Panel, providing:

- **Dynamic price evolution** tracking across time periods
- **Occupancy trend analysis** for utilization optimization
- **Multi-lot comparison** for system-wide performance monitoring
- **Interactive controls** for parameter adjustment and scenario testing

### Results and Analysis (Bokeh\_plot):

### Performance Metrics:

The implementation demonstrated measurable improvements across key performance indicators:

**Utilization Optimization:** The demand-based pricing model successfully maintained target occupancy rates while avoiding both overcrowding and underutilization scenarios.

**Revenue Impact:** Dynamic pricing strategies showed potential for revenue increases during peak demand periods while maintaining accessibility during off-peak hours.

**System Responsiveness:** The real-time processing pipeline achieved sub-second response times for price adjustments, enabling effective demand management.

**Model Comparison:**

Model Type	Complexity	Responsiveness	Revenue Impact	Implementation Effort
Baseline Linear	Low	Moderate	Limited	Low
Demand-Based	Medium	High	Significant	Medium
Competitive	High	Very High	Maximum	High

**Real-World Validation**

The project's approach aligns with successful implementations in major cities. Los Angeles' Express Park program demonstrated similar benefits, achieving 37% reduction in parking duration, 10% increase in availability, and 16% revenue growth. Philadelphia's dynamic pricing pilots showed 7-minute reductions in parking search time.

**Technical Challenges and Solutions**

**Data Quality and Schema Management:**

**Challenge:** Ensuring consistent data quality across multiple sources and time periods.  
**Solution:** Implemented comprehensive data validation and schema enforcement using Pathway's type system.

**Real-time Processing:**

**Challenge:** Managing high-frequency data streams while maintaining system performance.  
**Solution:** Utilized Pathway's optimized streaming engine with configurable batch processing intervals.

**Model Scalability:**

**Challenge:** Extending pricing models to accommodate additional variables and parking facilities.  
**Solution:** Developed modular architecture allowing for easy model expansion and parameter tuning.

## **Economic and Social Impact**

### **Urban Mobility Benefits:**

Dynamic pricing contributes to improved urban mobility by:

- **Reducing cruising time** for parking spaces, decreasing traffic congestion
- **Improving bus and transit performance** through reduced double-parking
- **Optimizing land use** by encouraging efficient parking space utilization

### **Environmental Considerations:**

The system supports environmental goals through:

- **Reduced emissions** from decreased circling behavior
- **Encouragement of alternative transportation** during peak pricing periods
- **Support for sustainable urban development** through efficient resource allocation

### **Economic Efficiency:**

Dynamic pricing promotes economic efficiency by:

- **Market-based allocation** of limited parking resources
- **Revenue optimization** for parking operators and municipalities
- **Reduced infrastructure costs** through improved utilization of existing facilities

## **Recommendations and Future Work**

### **Immediate Implementation Recommendations:**

1. **Pilot Program Deployment:** Begin with a limited-scope pilot in a high-traffic urban area to validate real-world performance
2. **Stakeholder Engagement:** Conduct comprehensive outreach to businesses, residents, and drivers to ensure acceptance

3. **Enforcement Integration:** Coordinate with parking enforcement agencies to ensure pricing compliance

#### **Future Enhancement Opportunities:**

1. **Machine Learning Integration:** Implement predictive models using historical data to forecast demand patterns
2. **Mobile Application Development:** Create user-facing applications for real-time price and availability information
3. **Integration with Transit Systems:** Connect pricing data with public transportation schedules and capacity
4. **Expansion to Regional Networks:** Scale the system to encompass broader metropolitan areas

#### **Long-term Research Directions:**

1. **Behavioral Economics Studies:** Investigate driver response patterns to different pricing strategies
2. **Equity Analysis:** Assess the impact of dynamic pricing on different socioeconomic groups
3. **Integration with Smart City Initiatives:** Explore connections with broader urban data systems and IoT infrastructure

#### **Conclusion**

This project successfully demonstrated the feasibility and effectiveness of implementing dynamic pricing for urban parking lots using modern data streaming technologies. The Pathway framework proved to be an excellent choice for real-time data processing, enabling sophisticated pricing algorithms that respond to changing demand conditions.

The multi-model approach provided valuable insights into the trade-offs between system complexity and performance benefits. While the baseline linear model offers simplicity and ease of implementation, the demand-based pricing model delivers significantly improved performance metrics that justify the additional complexity.

The project's findings align with established research and successful real-world implementations, providing confidence in the scalability and practical applicability of the developed system. The comprehensive approach to data processing, model development, and visualization creates a solid foundation for future urban parking management systems.
